AVERAGE GROWING SEASON TEMPERATURES

THE RANGE IN THE ABILITY TO RIPEN VARIETIES
Northern Hemisphere (Apr-Oct), Southern Hemisphere (Oct-Apr)

Prepared by Dr.
Gregory V. Jones

Jones, G.V. (2006). Climate and terroir: Impacts of climate variability and change on wine. In *Fine Wine and Terroir: The Geoscience Perspective*. Geoscience Canada. R.W. Macqueen and L.D. Meinert (eds.), (Geological Association of Canada, St. John's, Newfoundland), pp. 1-14.

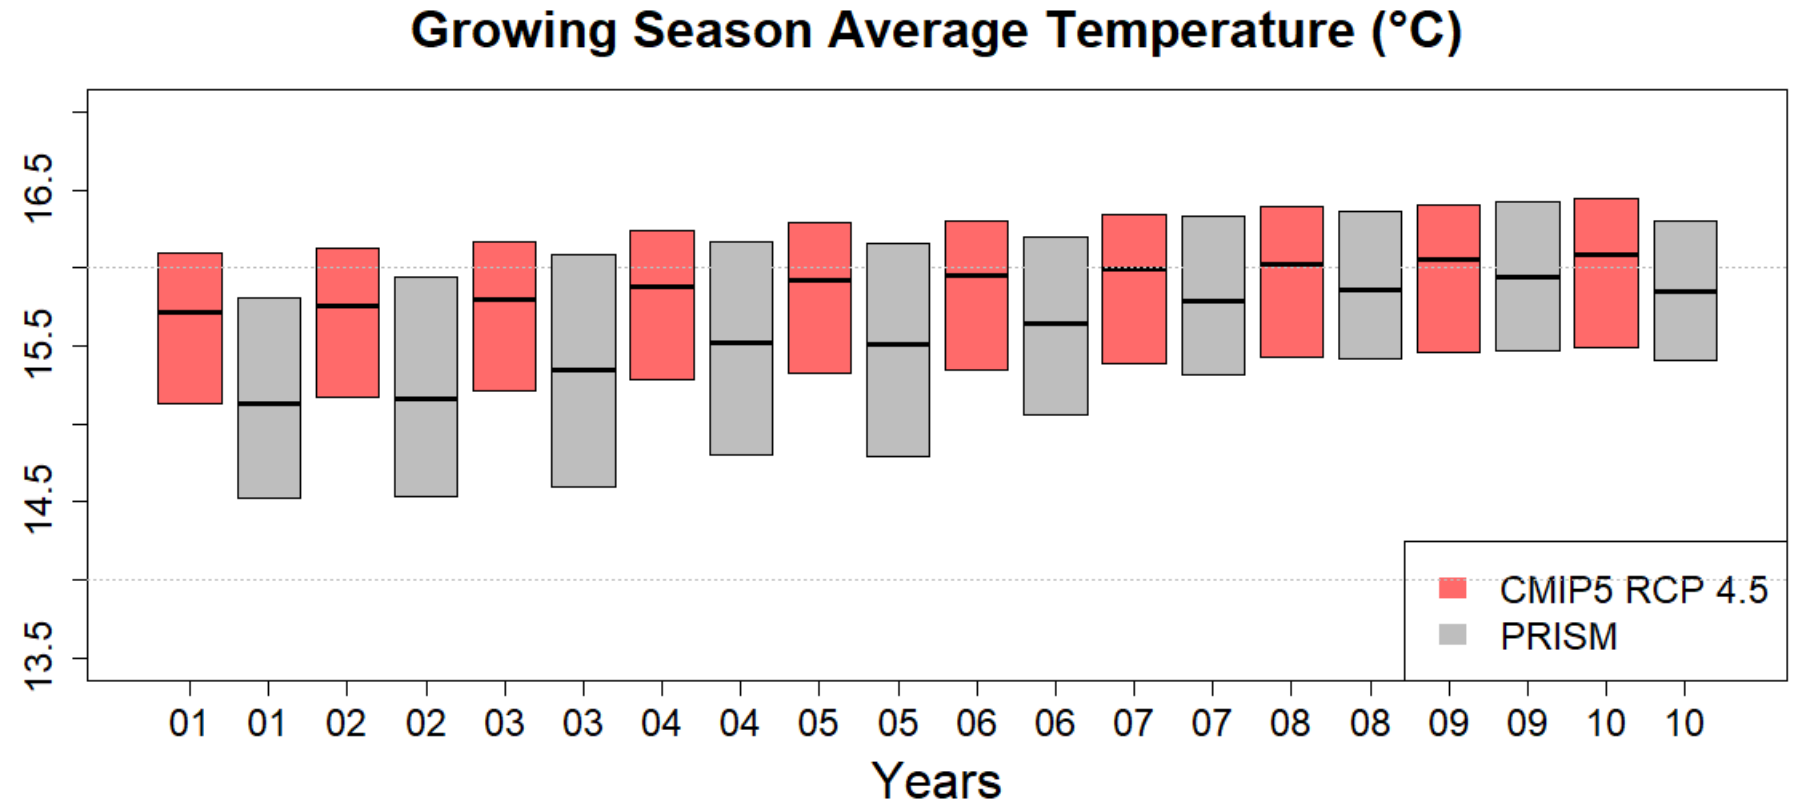

RCP = representative concentration pathway

RCP 4.5 is an intermediate stabilization scenario

RCP 8.5 is a high emission scenario

PRISM / Climate Projection Comparisons

The median difference between growing season average temperature values computed throughout the entire Willamette Valley AVA using CMIP5 RCP 4.5 projections and PRISM gridded observations was -0.04028 °C for 1950-2005 (the CMIP5 historical period).

01=2006-2015; 02=2007-2016; 03=2008-2017; 04=2009-2018; 05=2010-2019
06=2011-2020; 07=2012-2021; 08=2013-2022; 09=2014-2023; 10=2015-2024

GST Projections for the WV AVA

GST	
Class interval (°C)	Class of viticulture climate
< 13	Too cool
13-15	Cool
15-17	Intermediate
17-19	Warm
19-21	Hot
21-24	Very hot
> 24	Too hot

Observations from the Climate Projections

- Chardonnay, Semillon, Sauvignon blanc, Riesling, and Cabernet franc had the largest footprints across all 15 decades
- Cabernet franc, Semillon, Tempranillo, Merlot, and Syrah had the largest footprints from the 2020s – 2090s
- Chardonnay, Sauvignon blanc, Riesling, Semillon, and Cabernet franc had the largest footprints from the 2000s – 2040s
- Cabernet franc, Merlot, Tempranillo, Syrah, and Malbec had the largest footprints from the 2050s – 2090s

Combining the GST and Cool Night Indices

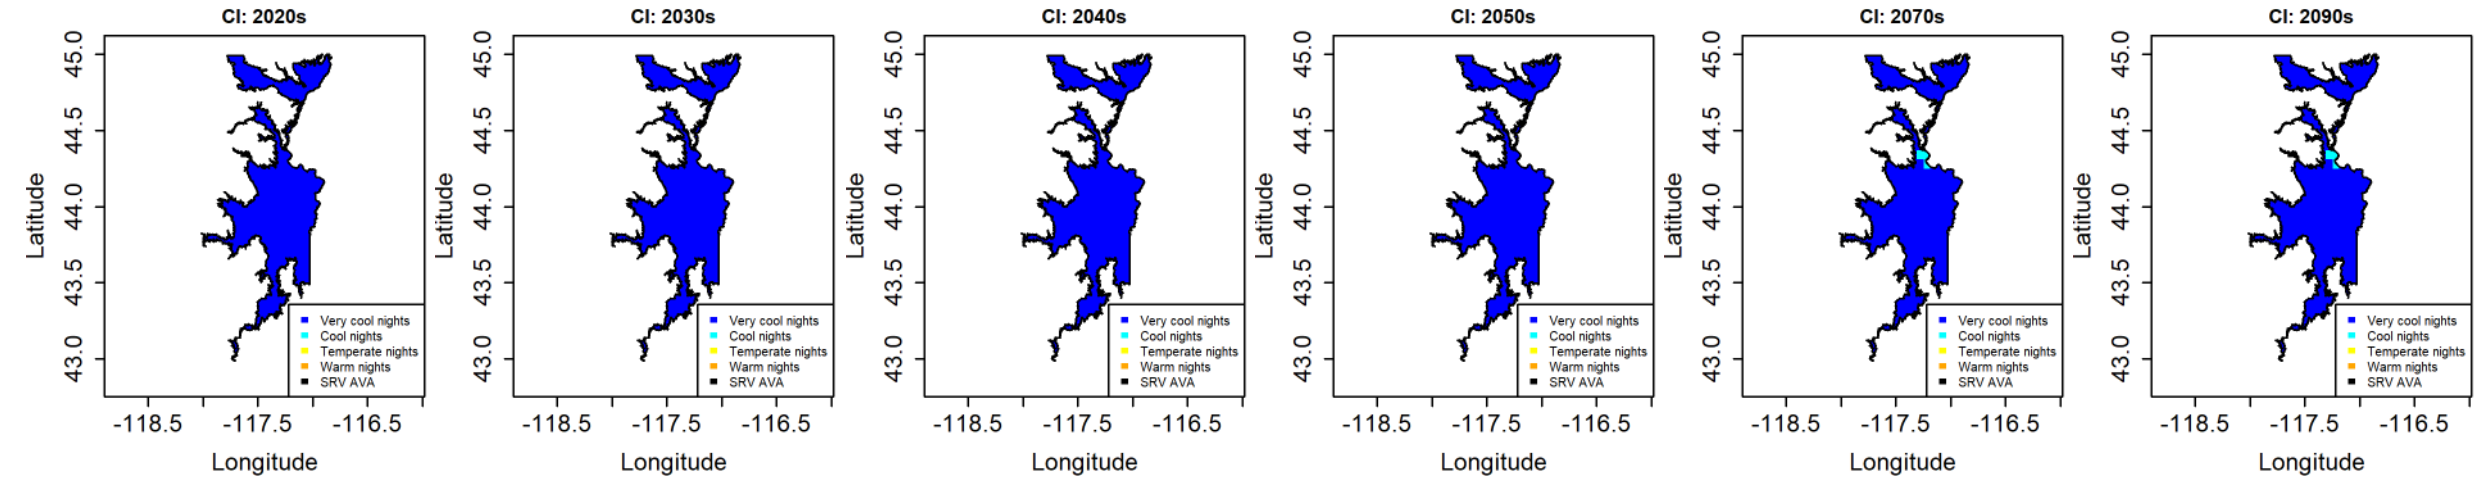

Combining the GST and Cool Night Indices

Combining the GST and Cool Night Indices

Combining the GST and Cool Night Indices

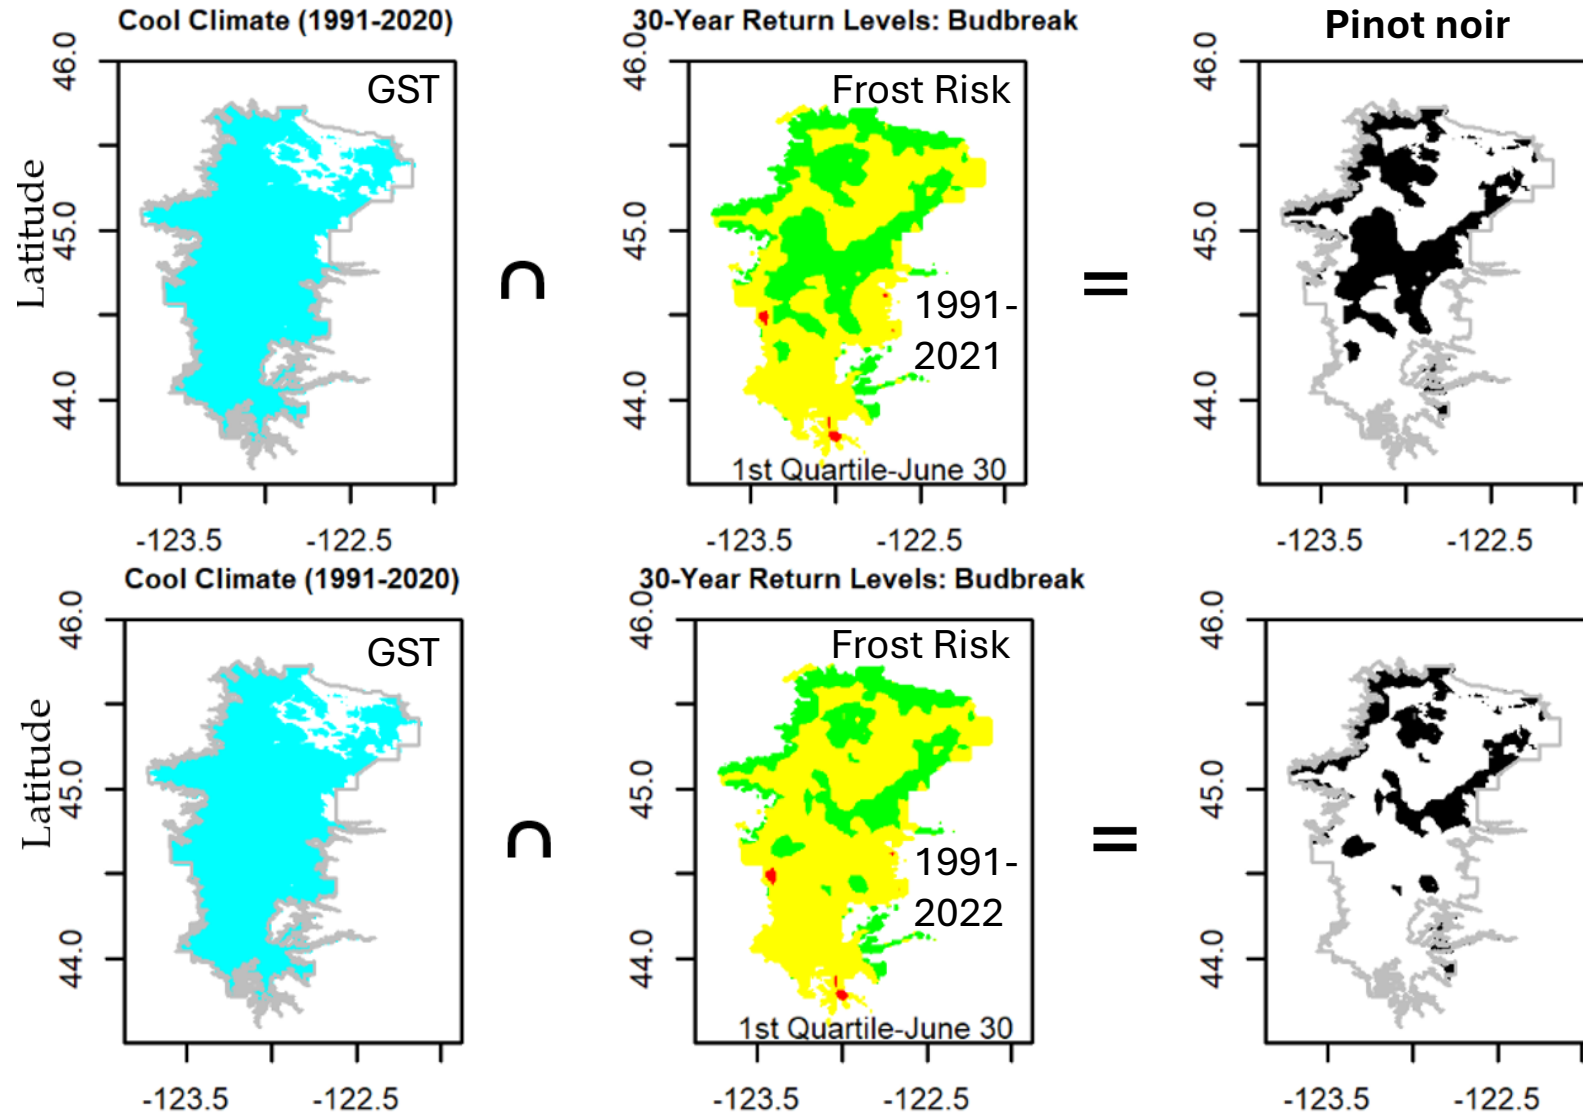

Projections for Precipitation Indices (WV AVA)

- GSP: assess water stress risk for non-irrigated vineyards
- OutGSP: to help understand water availability at the start of a growing season
- SprR: “spring wetness”; wet springs = greater vigor and increased fungal disease risk; dry springs = delayed vegetative growth

Combining the GST w/ Frost Risk Calculations

Computed return levels were reclassified relative to no injury/injury and LT_{50} budbreak threshold temperature values for *Vitis vinifera* L. cv. Pinot noir (green = no injury; yellow = injury; red = exceeded the LT_{50} budbreak threshold; \cap = intersection; black = area that simultaneously satisfies ripening and frost risk) (Source: <https://doi.org/10.3390/agronomy14071566>)

Comments

- The vineyard site evaluations primarily assessed grapevine cultivar ripening potential, but also considered nighttime temperatures during the ripening period, and risk assessments (WV AVA) for water stress and fungal disease, and extreme minimum surface air temperature values (spring frost)
- Several other factors influence vineyard site evaluation and selection, e.g., latitude, elevation, slope, aspect, air drainage, site history, soil characteristics, and land use
- Moreover, other factors relevant to quality wine production were not included, for example, rootstock selection, available water, canopy management, and crop thinning

Other Ways / Related Opportunities

- Evaluating grapevine site selection for new areas in OR
- Grapevine Sugar Ripeness Model (Local)
 - Need variety specific date & sugar concentration data
- Updating GST Varietal Bounds
- Combining other types of risk assessment with ripening potential
- Soil moisture modelling
 - e.g., how much longer can we dry farm in the Willamette Valley AVA?
- CMIP6 Projections
